解 1. (1). pointer(array(3, int))

- (2). array(3, pointer(int))
- (3). pointer(array(3, int))
- (4). pointer(array(3, pointer(int)))
- (5). array(3, pointer(pointer(int)))

解 2. 翻译方案为:

表 1: 翻译方案

```
P \rightarrow D \; ; \; E
D \rightarrow D_1 \; ; \; D_2 \mid id \; : \; T \; \{addtype(id.entry, T.type); \}
T \rightarrow list \; of \; T_1 \; \{T.type = list(T_1.type); \} \mid char \; \{T.type = char; \} \mid integer \; \{T.type = integer; \}
E \rightarrow (L) \; \{E.type = list(L.type); \} \mid literal \; \{E.type = char; \}
\mid num \; \{E.type = integer; \} \mid id \; \{E.type = gettype(id.entry); \} \mid nil \; \{E.type = NIL; \}
L \rightarrow E \; , \; L_1 \; \{if(E.type \; ! = \; L_1.type) \{L.type = type\_error; \} \; else\{L.type = L_1.type; \} \} \mid E \; \{L.type = E.type; \}
```

解 3. (a). (pointer(α)) × ($\beta \rightarrow \gamma$)

(b). $\beta \times (\gamma \to \delta)$

这两个表达式最一般的合一替换为:

 $S(\alpha) \to \alpha, \ S(\beta) \to pointer(\alpha), \ S(\gamma) \to pointer(\alpha), \ S(\delta) \to pointer(\alpha)$

得到合一表达式为: $(pointer(\alpha)) \times (pointer(\alpha) \rightarrow pointer(\alpha))$

若将 (b) 中 δ 换为 α ,则不存在合一替换.

解 4. 记 f 类型为 β, l 类型为 γ, map 类型为 θ. 则可得类型推导过程如下:

表 2: 类型推导过程

行	定型断言	代换	规则
(1)	f:eta		(Exp id)
(2)	$l:\gamma$		(Exp id)
(3)	map: heta		(Exp id)
(4)	$map(f,l):\delta$	$\theta = \beta \times \gamma \to \delta$	$(Exp\ FunCall)$
(5)	$null: list(\alpha_n) \to boolean$		(Exp Id Fresh)
(6)	null(l):boolean	$\gamma = list(\alpha_n)$	$(Exp\ FunCall)$
(7)	$nil: list(lpha_i)$		(Exp Id Fresh)
(8)	$hd: list(\alpha_p) \to \alpha_p$		(Exp Id Fresh)
(9)	$hd(l): lpha_n$	$\alpha_p = \alpha_n$	$(Exp\ FunCall)$
(10)	$f(hd(l)):\eta$	$\beta = \alpha_n \to \eta$	$(Exp\ FunCall)$
(11)	$tl: list(\alpha_q) \to \alpha_q$		(Exp Id Fresh)
(12)	$tl(l): list(lpha_n)$	$\alpha_q = \alpha_n$	$(Exp\ FunCall)$
(13)	$map(f,tl(l)):\delta$	$\gamma = \alpha \times list(\alpha_n) \to \delta$	$(Exp\ FunCall)$
(14)	$cost: \alpha_r \times list(\alpha_r) \to \alpha_r$		(Exp Id Fresh)
(15)	$cost(f(hd(l)), map(f, tl(l))) : list(\alpha_r)$	$ \eta = \alpha_r $ $ \delta = list(\alpha_r) $ $ \beta = \alpha_n \to \alpha_r $ $ \theta = ((\alpha_n \to \alpha_r) \times list(\alpha_n)) \to list(\alpha_r) $	$(Exp\ FunCall)$
(16)	$if:boolean \times \alpha_s \times \alpha_s \to \alpha_s$		(Exp Id Fresh)
(17)	$if():lpha_r$	$\alpha_i = \alpha_r$	$(Exp\ FunCall)$
(18)	$=: \alpha_t \times \alpha_t \to \alpha_t$		(Exp Id Fresh)
(19)	$map(f,l) = \dots : \alpha_r$	$\alpha_t = \alpha_r$	$(Exp\ FunCall)$

因此可以看出, map 的类型为: $((\alpha_n \to \alpha_r) \times list(\alpha_n)) \to list(\alpha_r)$. 因为 α_n, α_r 是未知类型的, 因此在前面加上任意符号, 可得: $\forall \alpha \forall \beta ((\alpha \to \beta) \times list(\alpha)) \to list(\beta)$
